

PROBLEM-SOLUTION FIT CANVAS

Domain: IT Service Management (ITSM) / Support Automation

Date01 October 2026		Team IDSWTID-2026-1536	
Project NameAUTO TICKET CLASSIFICATION USING FLOW DESIGN			
Primary: Helpdesk Leads, IT Service Managers, & Support Engineers handling high daily ticket volumes. Secondary: Enterprise Operations Teams and SaaS Support Teams seeking SLA optimization. Characteristics: Experiencing team fatigue, backlogs, and strict resolution time targets (SLAs).		Core Job: Route incoming support tickets quickly and accurately to the right specialized team/tier. Key Problems: High manual triage time, frequent misclassification of ticket priority/category, and delayed first response times.	
3. TRIGGERS What triggers customers to seek a solution? Spikes in ticket volume during product updates or system outages. Breached customer SLAs leading to poor CSAT scores. Support engineers complaining about manual repetitive triage work.		4. EMOTIONS: BEFORE / AFTER How do they feel before and after? Before: Overwhelmed, anxious about SLA breaches, frustrated by repetitive manual tagging. After: In control, confident, relaxed with transparent & automated ticket routing logic.	
5. AVAILABLE SOLUTIONS & ALTERNATIVES What solutions are currently used and what are their pros/cons? Manual Triage: Humans read and assign tickets. (High accuracy, but extremely slow & expensive). Keyword-based Rules: Basic IF/THEN rules. (Fast, but rigid, easily breaks, fails on semantic nuance). Black-Box ML Models: Standard AI classifiers. (Automated, but lack customizability & transparency).			
6. CONSTRAINTS What limits their choice of solutions? Lack of deep machine learning expertise in support teams. Tight budget for enterprise AI automation software. Strict data privacy rules prohibiting external model training.		7. BEHAVIOUR What do they do to manage the situation today? Assign dedicated "triage shifts" to senior engineers. Constantly edit complex, unwieldy rule lists in ticketing systems. Conduct weekly syncs to reassign misrouted tickets.	
8. CHANNELS OF BEHAVIOUR Where do these operational actions take place? 8.1 Online / SystemITSM Portals (Jira, Zendesk, ServiceNow), Webhooks, Slack/Teams alert channels, custom REST API pipelines. 8.2 Offline / ProcessDaily standups, support ops planning sessions, tier escalation meetings, SLA review board meetings.			
9. PROBLEM ROOT CAUSE Why does this problem fundamentally exist? Support tickets are written in unstructured human natural language with high variability. Static keyword matching cannot understand context or sentiment accurately.		10. PROPOSED SOLUTION: AUTO TICKET CLASSIFICATION USING FLOW DESIGN How does a visual flow-based classification engine bridge the gap? Visual Flow Canvas: Build modular, node-based classification logic (Ingest → Preprocess → NLP Intent Classifier → Conditional Routing Node → Escalation Node). Hybrid Classification: Combines structured flow logic with LLM/NLP nodes for high precision and fallback security. Full Explainability: Visual step-by-step audit logs show exactly why a ticket followed a specific classification path. No-Code Adaptability: Support leads can
